Project work

I worked on 4_Model.R, 5_Predictive.R as well as the proposal.qmd. Together with Sarah I filled out the group reflection. I added “my” answers to the index.qmd and corrected mistakes I found. I added the model plots as an image. I looked through every file and corrected mostly small mistakes as typos, labels or content issues. I also initiate the group meetings and firstly took care of having an overview of internal organization. Due to health issues, then Sarah took over having an overview and did a lot(!) for the whole project structure.

Sarah and I had a final discussion towards the end, in which we presented each other our results. Generally, she and I stayed mostly well in touch over the whole project. We discussed some final thoughts, i.e. I suggested alternative questions to the predictive question or which countries we should select for our final version, since she suggested using only 4.

I really enjoyed working on the predictive question, especially because I’m always having lots of fun with plotting. During working on that question I already noticed how the prediction (especially via a linear regression) seemed not very reliable. After receiving the feedback, which criticized the predictive question as well, I eventually decided to not take it into to final project, but only mention it instead. I still added it into the “Code” branch, so the work I did was still open to inspection. I really struggled finding a different question I was interested in but also included a model, which still fitted our variables and which matched our capacities.

I generally was interested in a lot of questions concerning the large data set we used, but getting familiar with the variables was indeed an obstacle. I would’ve especially wanted to compare variables as maternal and paternal leave, different types of compensations and other possible socio-economical correlations, but we chose the “final-original” three questions, and therefore the used variables, as a team.

LLM Usage

If I used LLMs it was reduced to ChatGPT to clean my code or to -ironically- finding very basic errors (such as typos, being in the wrong path, forgot loading the data or a package), before frustrating too much. Therefore, I really got familiar with basic codes as `getwd()`. Since I was somehow very insecure about my statistical models and interpretations in the project itself, I used ChatGPT as a second opinion, which mostly agreed to what I did. I also asked it for alternative models for the predictive question, since linear regression as well as a polynomial regression didn’t seem correct, but its recommendations were a little too complex for my knowledge.

Future motivation

In hindsight, I wish I used the console more to also work on the git repository. Generally, I do think I got a little more familiar with GitHub, since I’ve never used it before, but I know that I could’ve used its functions even more. I’m also inspired to work with python and on more complex projects, knowing what I should consider now.
